Smithsonian

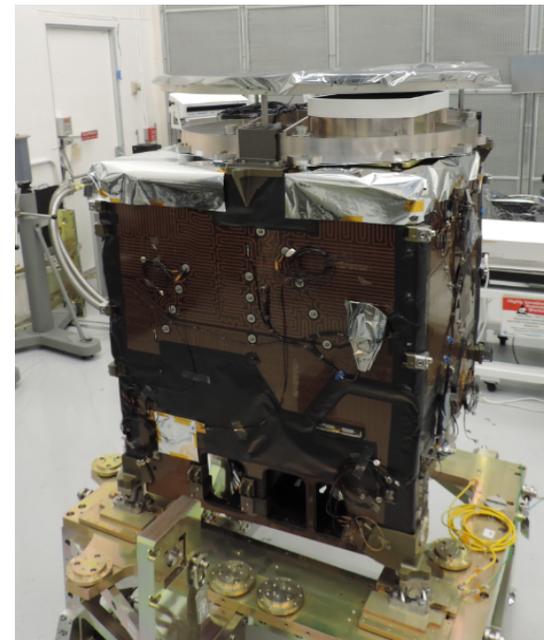

- The TEMPO instrument successfully completed all environmental testing, was accepted by NASA & SAO, and was safely placed into storage.
- Performance meets or exceeds data product requirements.

# Status of TEMPO hosting

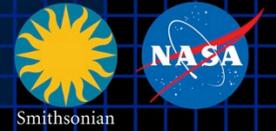

- NASA, in coordination with the USAF's Space and Missile Systems Center (SMC), released the TEMPO Hosting Services Request for Proposal (RFP) on March 13, 2019.
- The RFP solicited bids to be delivered by April 29, 2019 for a TEMPO Delivery Order under the Hosted Payloads Solutions (HoPS).
- Responses are currently being evaluated by the NASA/USAF team.
- Contract award is planned for approximately July 2019.

- The green paper will be presented at an SPIE meeting in September. It will then become an SPIE publication.
- Please feel free to suggest additions and corrections through at least July. New authors welcome.

# TEMPO spectral coverage

TEMPO East/West Pixel Size

TEMPO North/South Pixel Size

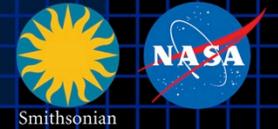

Location	N/S (km)	E/W (km)	GSA (km <sup>2</sup> )
36.5°N, 100°W	2.11	4.65	9.8
Washington, DC	2.37	5.36	11.9
Seattle	2.99	5.46	14.9
Los Angeles	2.09	5.04	10.2
Boston	2.71	5.90	14.1
Miami	1.83	5.04	9.0
Mexico City	1.65	4.54	7.5
Canadian tar sands	3.94	5.05	19.2

**Assumes 2000 N/S pixels**

**For GEO at 80°W, pixel size at 36.5°N, 100°W is 2.2 km × 5.2 km.**

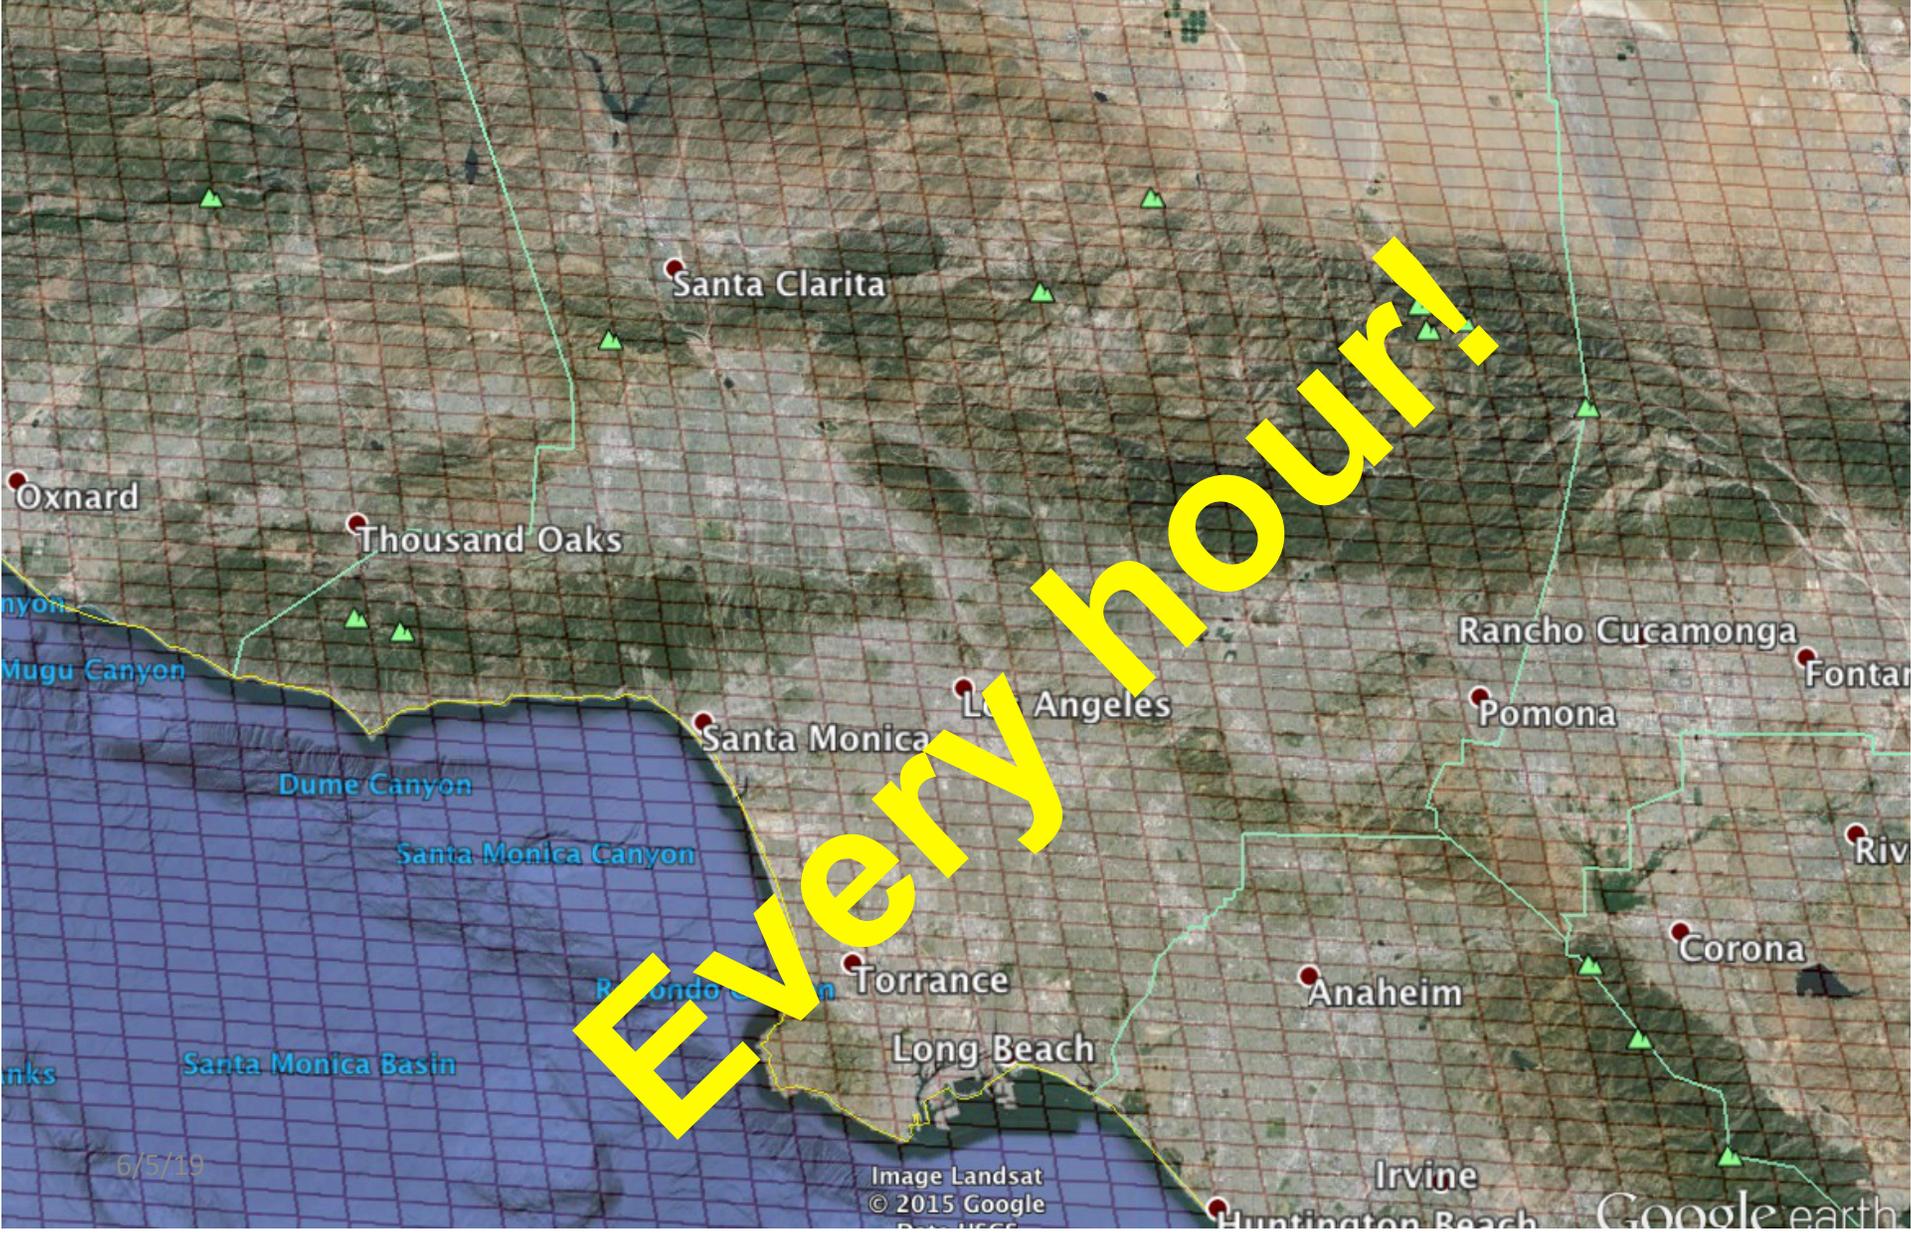

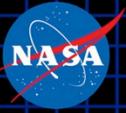

# DC and Baltimore coverage

TEMPO hourly footprints overlaid on the Baltimore-Washington metropolitan area. The footprint size here is 2.4 km N/S × 5.4 km E/W. Map created using Google Earth/Landsat Imagery.

# TEMPO instrument

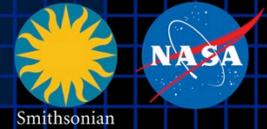

## TEMPO instrument characteristics

Wavelength range	290-490 + 540-740 nm
Spectral resolution	0.6 nm FWHM
Spectral sampling	0.2 nm
Maximum S/N	2700 @ 330-340 nm, EOL
Spatial resolution	2.1×4.5 km <sup>2</sup> @ 36.5N, 100W
Spectra per hour	2000 N/S × 1250 E/W

# Baseline and threshold data products

Species/Products	Required Precision	Temporal Revisit
0-2 km O <sub>3</sub> (Selected Scenes) <b>Baseline only</b>	10 ppbv	2 hour
Tropospheric O <sub>3</sub>	10 ppbv	1 hour
Total O <sub>3</sub>	3%	1 hour
Tropospheric NO <sub>2</sub>	$1.0 \times 10^{15}$ molecules cm <sup>-2</sup>	1 hour
Tropospheric H <sub>2</sub> CO	$1.0 \times 10^{16}$ molecules cm <sup>-2</sup>	3 hour
Tropospheric SO <sub>2</sub>	$1.0 \times 10^{16}$ molecules cm <sup>-2</sup>	3 hour
Tropospheric C <sub>2</sub> H <sub>2</sub> O <sub>2</sub>	$4.0 \times 10^{14}$ molecules cm <sup>-2</sup>	3 hour
Aerosol Optical Depth	0.10	1 hour

- **Minimal set of products sufficient for constraining air quality**
- **Across Greater North America (GNA): 18°N to 58°N near 100°W, 67°W to 125°W near 42°N**
- **Data products at urban-regional spatial scales**
  - Baseline ≤ 60 km<sup>2</sup> at center of Field of Regard (FOR)
  - Threshold ≤ 300 km<sup>2</sup> at center of FOR
- **Temporal scales to resolve diurnal changes in pollutant distributions**
- **Up to 25% special observations, with 10 minute or better resolution**
- **Additional products include H<sub>2</sub>O, HONO, BrO, IO, UV index**
- **Geolocation uncertainty of less than 4 km**
- **Mission duration, subject to instrument availability**
  - Baseline 20 months
  - Threshold 12 months
  - Extendable in 2-year increments

# TEMPO science questions

1. What are the temporal and spatial variations of **emissions** of gases and aerosols important for air quality and climate?
2. How do physical, chemical, and dynamical **processes** determine tropospheric composition and air quality over scales ranging from urban to continental, diurnally to seasonally?
3. How does air pollution drive **climate** forcing and how does climate change affect air quality on a continental scale?
4. How can observations from space improve **air quality forecasts and assessments** for societal benefit?
5. How does **intercontinental transport** affect air quality?
6. How do **episodic events**, such as wild fires, dust outbreaks, and volcanic eruptions, affect atmospheric composition and air quality?

TEMPO's hourly measurements allow better understanding of the complex chemistry and dynamics that drive **air quality on short timescales**. The density of TEMPO data is ideally suited for data assimilation into chemical models for both air quality forecasting and for better constraints on emissions that lead to air quality exceedances. Planning is underway to combine TEMPO with regional air quality models to **improve EPA air quality indices and to directly supply the public with near real time pollution reports and forecasts through website and mobile applications**. As a case study, an OSSE for the Intermountain West was performed to explore the potential of geostationary ozone measurements from TEMPO to improve monitoring of ozone exceedances and the role of background ozone in causing these exceedances (Zoogman *et al.* 2014).

**Aerosols** TEMPO's launch algorithm for retrieving aerosols will be based upon the OMI aerosol algorithm that uses the sensitivity of near-UV observations to particle absorption to retrieve **absorbing aerosol index** (AAI), **aerosol optical depth** (AOD) and **single scattering albedo** (SSA). TEMPO will derive its pointing from one of the **GOES-17** or **GOES-17** satellites and is thus automatically co-registered. TEMPO may be used together with the advanced baseline imager (ABI) instrument, particularly the  $1.37\mu\text{m}$  bands, for aerosol retrievals, reducing AOD and fine mode AOD uncertainties from 30% to 10% and from 40% to 20%.

**Clouds** The launch cloud algorithm is be based on the rotational Raman scattering (RRS) cloud algorithm that was developed for OMI by NASA GSFC. Retrieved cloud pressures from OMCLDRR are not at the geometrical center of the cloud, but rather at the optical centroid pressure (OCP) of the cloud.

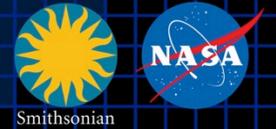

**Additional** cloud products are possible using the  $\text{O}_2\text{-O}_2$  collision complex and/or the  $\text{O}_2$  *B* band.

- **Measurement technique**
  - Imaging grating spectrometer measuring solar backscattered Earth radiance
  - Spectral band & resolution: 290-490 + 540-740 nm @ 0.6 nm FWHM, 0.2 nm sampling
  - 2 2-D, 2k×1k, detectors image the full spectral range for each geospatial scene
- **Field of Regard (FOR) and duty cycle**
  - Mexico City/Yucatan, Cuba to the Canadian oil sands, Atlantic to Pacific
  - Instrument slit aligned N/S and swept across the FOR in the E/W direction, producing a radiance map of Greater North America in one hour
  - **10 minutes!**
- **Spatial resolution**
  - 2.1 km N/S × 4.7 km E/W native pixel resolution (9.8 km<sup>2</sup>)
  - Co-add/cloud clear as needed for specific data products
- **Standard data products and sampling rates**
  - Most sampled hourly, including eXceL O<sub>3</sub> (troposphere, PBL)
  - NO<sub>2</sub>, H<sub>2</sub>CO, C<sub>2</sub>H<sub>2</sub>O<sub>2</sub>, SO<sub>2</sub> sampled hourly (average results for ≥ 3/day if needed)
  - Nominal spatial resolution 8.4 km N/S × 4.7 km E/W at center of domain (can often measure 2.1 km N/S × 4.7 km E/W)
  - Measurement requirements met up to 50° for SO<sub>2</sub>, 70° SZA for other products

# Traffic, biomass burning

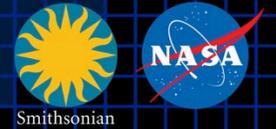

**Morning and evening higher-frequency scans** The optimized data collection scan pattern during mornings and evenings provides multiple advantages for addressing TEMPO science questions. The increased frequency of scans coincides with peaks in vehicle miles traveled on each coast.

**Biomass burning** The unexplained variability in ozone production from fires is of particular interest. The suite of  $\text{NO}_2$ ,  $\text{H}_2\text{CO}$ ,  $\text{C}_2\text{H}_2\text{O}_2$ ,  $\text{O}_3$ ,  $\text{H}_2\text{O}$ , and aerosol measurements from TEMPO is well suited to investigating how the chemical processing of primary fire emissions effects the secondary formation of VOCs and ozone. For particularly important fires it is possible to command special TEMPO observations at even shorter than hourly revisit time, as short as 10 minutes.

# NO<sub>x</sub> studies

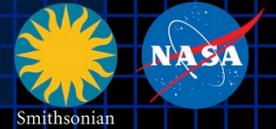

**Lightning NO<sub>x</sub>** Interpretation of satellite measurements of tropospheric NO<sub>2</sub> and O<sub>3</sub>, and upper tropospheric HNO<sub>3</sub> lead to an overall estimate of  $6 \pm 2$  Tg N y<sup>-1</sup> from lightning [Martin et al., 2007]. TEMPO measurements, including tropospheric NO<sub>2</sub> and O<sub>3</sub>, can be made for time periods and longitudinal bands selected to coincide with large thunderstorm activity, including outflow regions, with fairly short notice.

**Soil NO<sub>x</sub>** Jaeglé et al. [2005] estimate 2.5 - 4.5 TgN y<sup>-1</sup> are emitted globally from nitrogen-fertilized soils, still highly uncertain. The US a posteriori estimate for 2000 is  $0.86 \pm 1.7$  TgN y<sup>-1</sup>. For Central America it is  $1.5 \pm 1.6$  TgN y<sup>-1</sup>. They note an underestimate of NO release by nitrogen-fertilized croplands as well as an underestimate of rain-induced emissions from semiarid soils.

TEMPO is able to follow the temporal evolution of emissions from croplands after fertilizer application and from rain-induced emissions from semi-arid soils. Higher than hourly time resolution over selected regions may be accomplished by special observations. Improved constraints on soil NO<sub>x</sub> emissions may also improve estimated of lightning NO<sub>x</sub> emissions [Martin *et al.* 2000].

# Spectral indicators

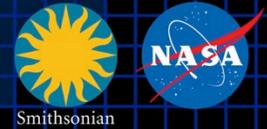

**Fluorescence and other spectral indicators** Solar-induced fluorescence (SIF) from chlorophyll over both land and ocean will be measured. In terrestrial vegetation, chlorophyll fluorescence is emitted at red to far-red wavelengths (~650-800 nm) with two broad peaks near 685 and 740 nm, known as the red and far-red emission features. Oceanic SIF is emitted exclusively in the red feature. SIF measurements have been used for studies of **tropical dynamics**, **primary productivity**, the length of the **carbon uptake** period, and **drought responses**, while ocean measurements have been used to detect red **tides** and to conduct studies on the physiology, phenology, and productivity of **phytoplankton**. TEMPO can retrieve both red and far-red SIF by utilizing the property that SIF fills in solar Fraunhofer and atmospheric absorption lines in backscattered spectra normalized by a reference (e.g., the solar spectrum) that does not contain SIF.

TEMPO will also be capable of measuring **spectral indices developed for estimating foliage pigment contents and concentrations**. Spectral approaches for estimating pigment contents apply generally to leaves and not the full canopy. A single spectrally invariant parameter, the **Directional Area Scattering Factor** (DASF), relates canopy-measured spectral indices to pigment concentrations at the leaf scale.

**UVB** TEMPO measurements of daily UV exposures build upon heritage from OMI and TROPOMI measurements. Hourly cloud measurements from TEMPO allow taking into account diurnal cloud variability, which has not been previously possible. The OMI UV algorithm is based on the TOMS UV algorithm. The specific products are the downward spectral irradiance at the ground (in  $W m^{-2} nm^{-1}$ ) and the erythemally weighted irradiance (in  $W m^{-2}$ ).

## Data products, science studies (the Green Paper), special operations

Volcanic **SO<sub>2</sub>** (column amount and plume altitude is a potential research product. Diurnal out-going **shortwave radiation and cloud forcing** is a potential research product.

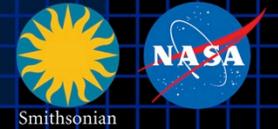

Nighttime “**city lights**” products, which represent anthropogenic activities at the same spatial resolution as air quality products, may be produced twice per day (late evening and early morning) as a research product. Meeting TEMPO measurement requirements for NO<sub>2</sub> (visible) implies the sensitivity for city lights products over the CONUS within a 2-hour period at  $2 \times 4.5 \text{ km}^2$  to  $1.1 \times 10^{-8} \text{ W cm}^{-2} \text{ sr}^{-1} \mu\text{m}^{-1}$ .

Several additional **first-measurement molecules** are being studied.

**H<sub>2</sub>O** will be produced at launch from the 7v vibrational polyad at 445 nm. Water vapor retrieved from the visible spectrum has good sensitivity to the planetary boundary layer, since the absorption is optically thin, and is available over both the land and ocean. The hourly coverage of TEMPO will greatly improve the knowledge of water vapor’s diurnal cycle and make rapid variations in time readily observed.

# Halogens

**BrO** will be produced at launch, assuming stratospheric AMFs. Scientific studies will correct retrievals for tropospheric content. **IO** was first measured from space by SAO using SCIAMACHY spectra [Saiz-Lopez *et al.*, 2007]. It will be produced as a scientific product, particularly for coastal studies, assuming AMFs appropriate to lower tropospheric loading.

**The atmospheric chemistry of halogen oxides over the ocean, and in particular in coastal regions**, can play important roles in ozone destruction, oxidizing capacity, and dimethylsulfide oxidation to form cloud-condensation nuclei [Saiz-Lopez and von Glasow, 2012]. The budgets and distribution of reactive halogens along the coastal areas of North America are poorly known. Therefore, providing a measure of the budgets and diurnal evolution of coastal halogen oxides is necessary to understand their role in atmospheric photochemistry of coastal regions. Previous ground-based observations have shown enhanced levels (at a few pptv) of halogen oxides over coastal locations with respect to their background concentrations over the remote marine boundary layer [Simpson *et al.*, 2015]. Previous global satellite instruments lacked the sensitivity and spatial resolution to detect the presence of active halogen chemistry over mid-latitude coastal areas. TEMPO observations together with atmospheric models will allow examination of the processes linking ocean halogen emissions and their potential impact on the oxidizing capacity of coastal environments of North America.

TEMPO also performs **hourly measurements of one of the world's largest salt lakes: the Great Salt Lake in Utah**. Measurements over Salt Lake City show the highest concentrations of BrO over the globe. Hourly measurement at a high spatial resolution can improve understanding of BrO production in salt lakes.
