GMAP & SIJAQ overview

SIJAQ : Satellite Integrated Joint monitoring (Studies) of Air Quality

Pre-SIJAQ(GMAP): GEMS Map of Air Pollution

Background

- Succession of KORUS-AQ (2016.5~6)
- In depth analysis on high PM pollution in winterValidation of Geostationary Environment Monitoring Spectrometer (GEMS), the world's first Geostationary Earth Orbit (GEO) environmental satellite

Time schedule for SIJAQ and GMAP

SIJAQ background

- 2016 vs 2021

PM₁₀ -21% ↘

PM_{2.5} -24% ↘

 Nitrate ↘
 OC ↗

No linear relationship between NO_2 and Nitrate for last 6 years (2016~2021)

Nitrate production depends on photochemical oxidation during the day as well as heterogeneous reactions at the aerosol surface. (Lim et al., 2022).

When high PM occurs, aerosols are in a liquid state and have a larger volume mean diameter (Song et al., 2022)

The physical state of aerosols affects the reaction with gaseous pollutants and heterogeneous reaction

SIJAQ background

Results

Spatial distribution of NO₂ Total VCD over SMA region

October 2021, Lon & Lat by 0.05°, CF <0.3, QAflag and SZA <85°

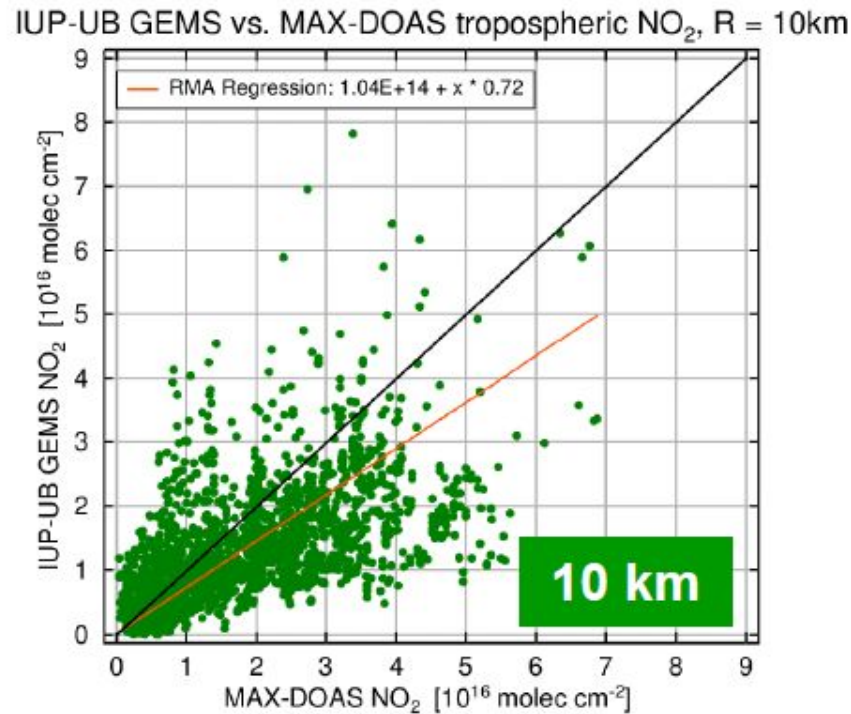

- Slightly different spatial distribution pattern of NO₂ Total VCD between TROPOMI and GEMS, due to different sampling time.
- Time-matched GEMS NO₂ Total VCD > TROPOMI NO₂ Total VCD

4 GMAP 2021

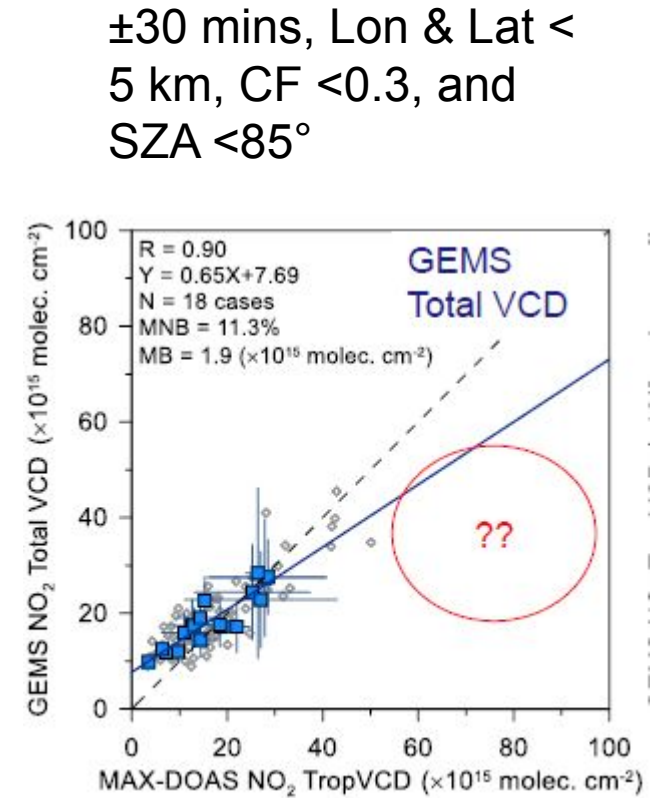

- High correlation, low bias, and high scatter (or rmse) for NO₂ VCD

Satellite Integrated Joint Monitoring for Air Quality study (SIJAQ)

Purpose

- **Characterizing hot spots in East Asia**
 - Urban pollution, industrial complex, coal-fire power plant, biomass burning, volcanic eruption, wild fire, etc.
- **Investigating processes controlling high PM_{2.5} events in winter**
 - Unidentified aerosol formation mechanism (heterogeneous reaction, nighttime chemistry, medium-range transport, etc.)
- **Analyzing the impact of emission change**
 - Recent change in energy-related and agricultural emissions in East Asia
- **Validating GEMS performance beyond Korea**

SIJAQ/ASIA-AQ emission inventory \Rightarrow Forward validation

Validation with in-situ obs. (SMA)

03.09 – 03.14

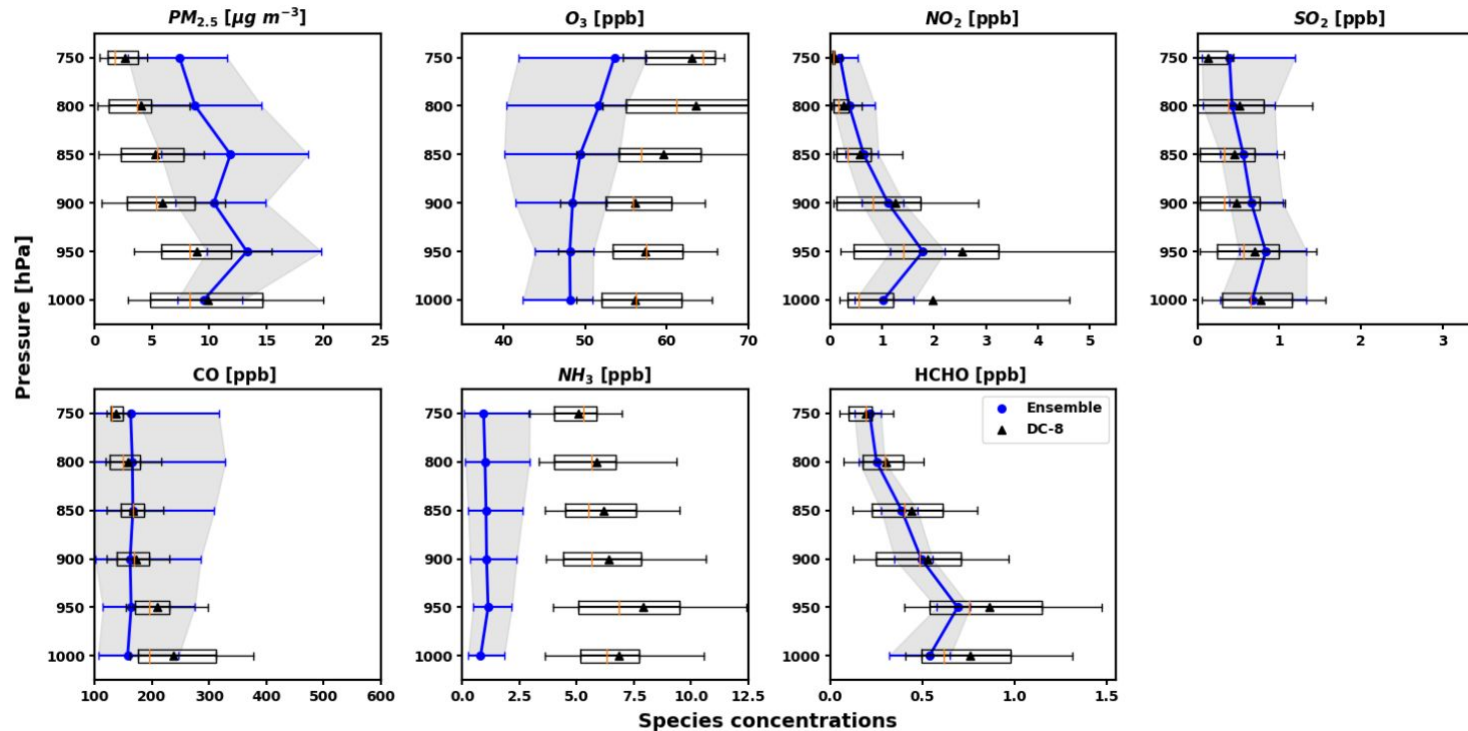

The scatter plots of the ensemble (MOD) and observations (OBS) are consistent, but MOD tends to underestimate OBS at specific high concentrations.

Note that looking at the individual model results for NO₂ simulation, the correlation coefficients are high at 0.57 to 0.75, indicating that the most models simulate the high NO₂ concentrations in the Seoul metropolitan area quite well

SIJAQ/ASIA-AQ emission inventory ⇒ Forward

validation

Simulated vs. Observed mean vertical profiles (KOREA)
DC-8 flight period

In the case of $PM_{2.5}$, the observed and predicted values showed a clear difference depending on the altitude. The predicted values of the ensemble model were higher than the observed values at all altitudes. The difference between them was greater in the lower and middle layers of the atmosphere than at the ground surface.

In the case of O_3 , the ensemble model showed a tendency to under-simulate the observed concentration by about 10 ppbv at all altitudes.

In the case of NO_2 , the observed values and the predicted values of the model were similar at all altitude. In particular, the observed values were the highest at an altitude of 950 hPa, and the ensemble model also showed the highest concentration.

In the case of CO , the ensemble model showed similar values to the observed values at all altitudes.

In the case of NH_3 , the vertical concentration distribution showed the largest difference between the observed values and the predicted values of the model. The NH_3 concentrations observed at DC-8 were outside the range of the ensemble model predictions as well as the inter-model range at all altitudes (NMB: -77%).

For $HCHO$, the observations and the model were in fairly good agreement at most altitudes.

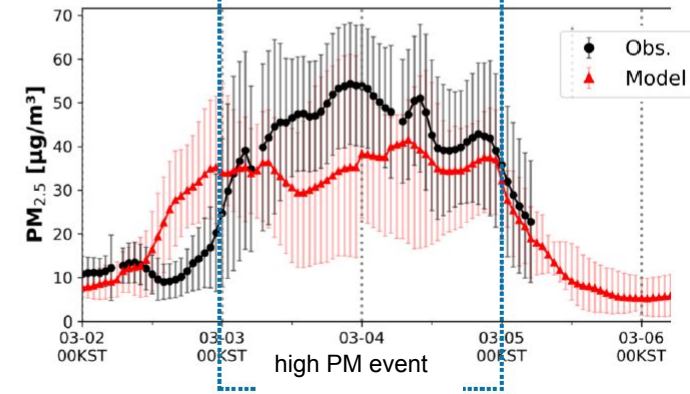

For SO_2 , there was a high degree of agreement between the observed and predicted values at most altitudes.

SIJAQ/ASIA-AQ emission inventory ⇒ Forward validation

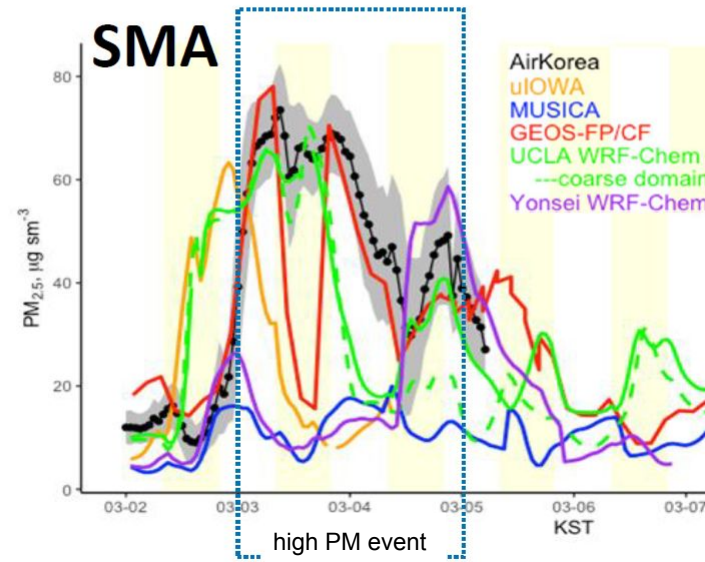

SMA

S.Korea

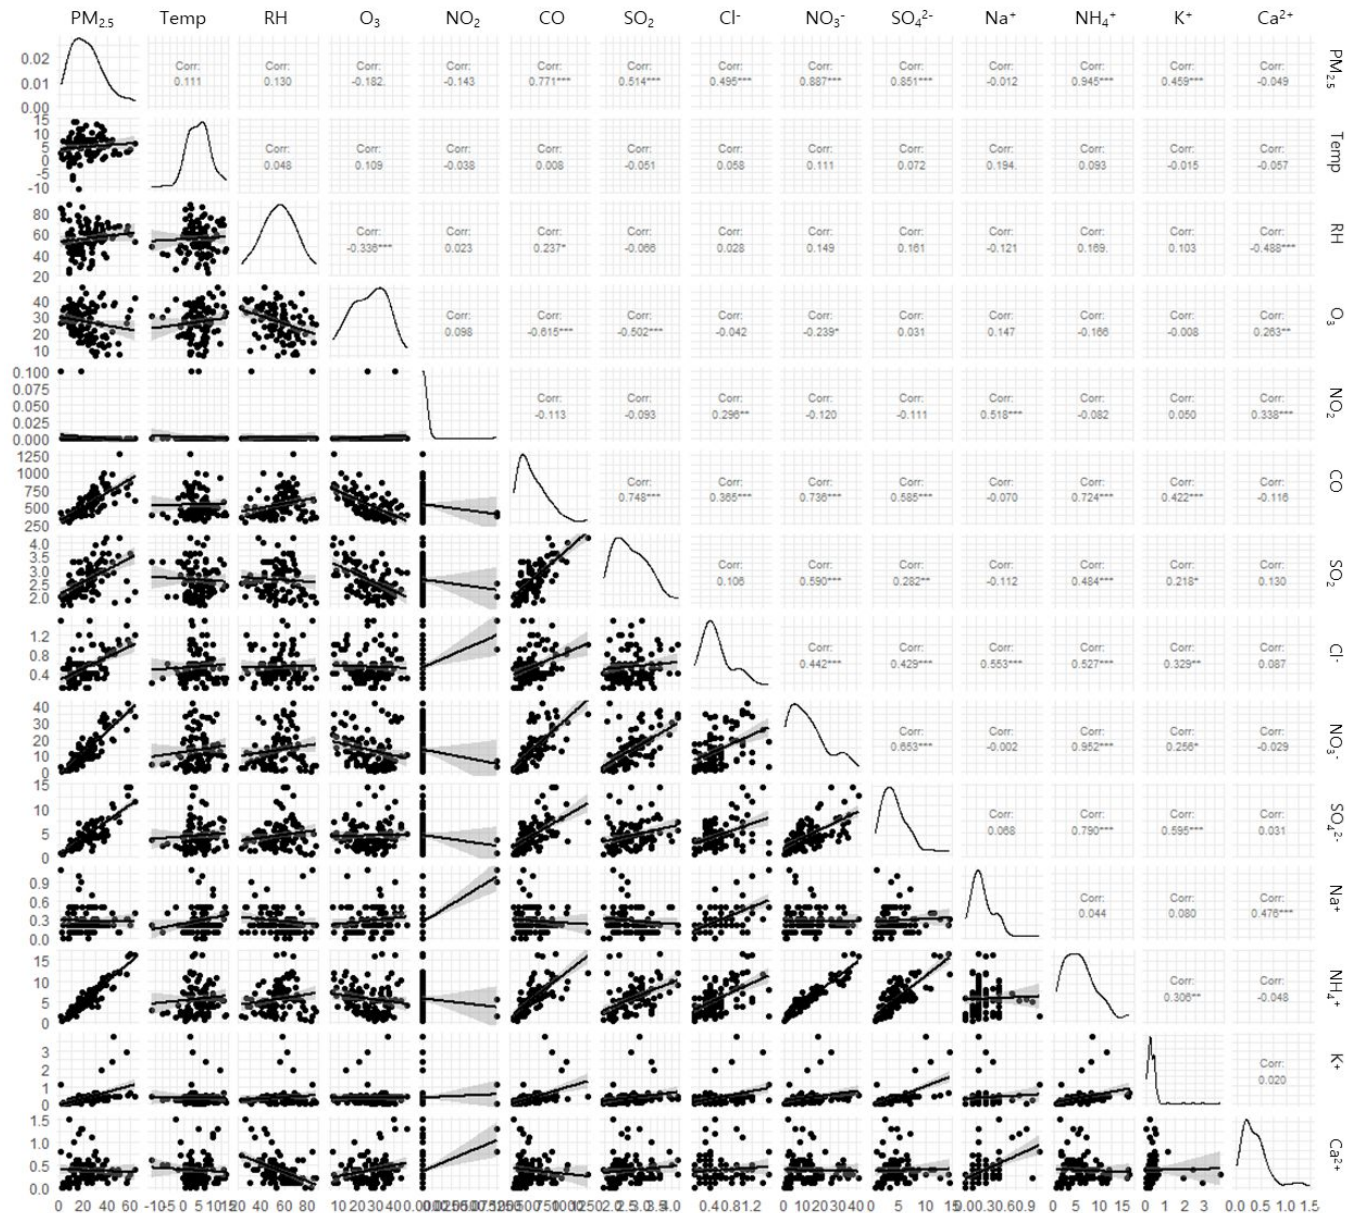

High PM event (3~4 March, 2024)
Model comparison with AirKorea

The ensemble model predictions showed under-simulation compared to the observations. In the case of the ensemble predictions, both the metropolitan area and South Korea showed a maximum concentration of about $40 \mu\text{g m}^{-3}$, showing a large difference from the observations.

During the period of high concentration of particulate matter, the GEOS-FP/CF model simulated the highest concentrations similar to the observations, but the simulated PM_{2.5} concentrations showed large variability even during the high concentration period. In addition, in the case of UCLA WRF-Chem, the onset and end of the high concentration particulate matter phenomenon appeared faster than the observations, suggesting that the uncertainty of the synoptic meteorological field was large. Other models did not simulate the high concentration particulate matter phenomenon at all, or the high concentration ended in a short period (uIOWA model).

Nitrate production mechanism in low temperature and high humidity environment

PM_{2.5} 0~35 μg/m³ vs PM_{2.5} 35 μg/m³

PM _{2.5} (μg/m ³)	Mean	
	0 ~ 35	>35
Temp (°C)	4.5	4.5
RH (%)	54.6	58.9
WS (m/s)	1.7	1.4
NO ₃ ⁻ (μg/m ³)	9.4	30.1
SO ₄ ²⁻ (μg/m ³)	3.6	8.1
NH ₄ ⁺ (μg/m ³)	4.4	11.4
Cl ⁻ (μg/m ³)	0.5	0.9
Na ⁺ (μg/m ³)	0.3	0.3
K ⁺ (μg/m ³)	0.3	0.8
Ca ²⁺ (μg/m ³)	0.4	0.3
Mg ²⁺ (μg/m ³)	0.1	0.1

Vertical profiles of HONO and NO₂

In the case of NO₂, the concentrations increased at low altitudes during the morning rush hour and decreased as the PBL grew during the day, whereas concentrations at high altitudes increased progressively, suggesting that diurnal variations in ground-level air pollutants may differ from those in the upper atmosphere.

In the case of HONO, the concentrations were highest at night regardless of altitude and showed a pattern of decreasing during the day due to photolysis

SIJAQ/ASIA-AQ

Analysis of chemical composition characteristics below 1 km altitude among airborne observations during the ASIA-AQ period.

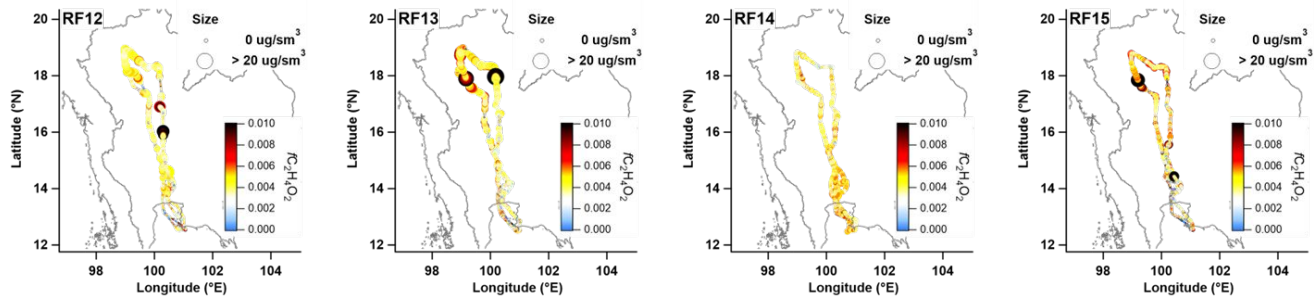

In Korea, **OA** showed a clear boundary between the sea and the inland. In the West Sea, OA was distributed higher as PM_{1.0} increased, reaching a composition ratio of OA in PM_{1.0} of approximately 80%. In the inland, OA decreased as PM_{1.0} increased, and especially in the area near Seoul (126.7~127°E), which is the city center, it decreased to approximately 23%.

Sulfate was observed to have a higher composition ratio as PM_{1.0} decreased, and there was no particular difference between the land and the sea.

Nitrate showed a composition ratio opposite to OA and sulfate. Nitrate existed very limitedly in PM_{1.0} when the concentration was low, and was observed to have a lower composition ratio in the sea than in the inland. Nitrate increased its chemical composition ratio to about 44% along with the increase in PM_{1.0} concentration. This means that nitrate is a major chemical component that has a greater impact on the increase in PM_{1.0} inland in Korea than OA and sulfate, and

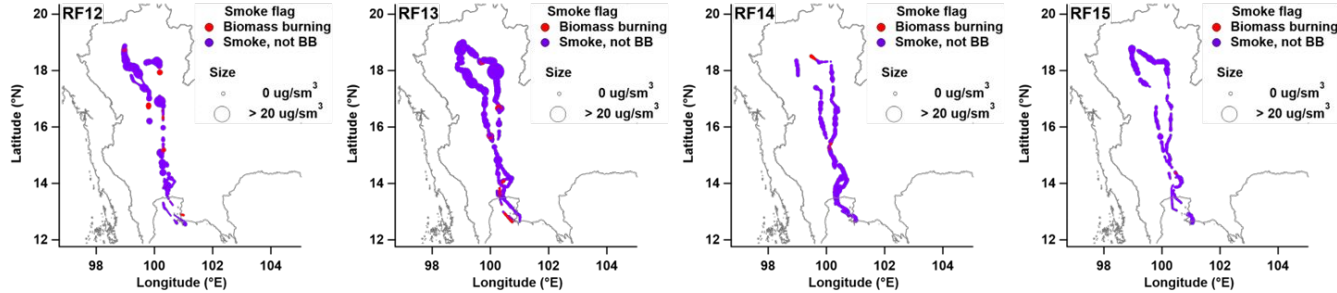

SIJAQ/ASIA-AQ

Levoglucosan:OA

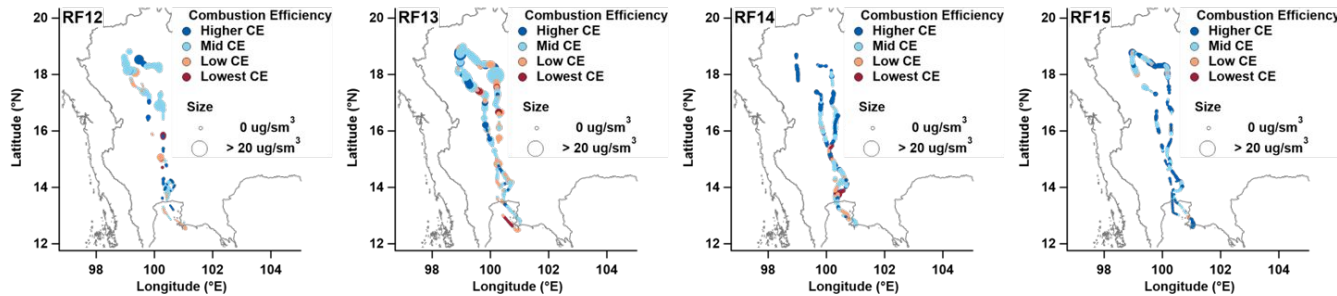

The levoglucosan:OA ratios measured by HR-ToF-AMS were above 0.003 in most areas, indicating the influence of **biomass burning**.

Smoke flag

In the smoke flags, most areas of Thailand, including Chiang Mai, were analyzed as **simple smoke, not biomass burning**, and the combustion efficiency was also analyzed as high or medium combustion efficiency, not the lowest combustion efficiency, which is the influence of biomass burning

Combustion efficiency

The smoke flags were classified into three types: non-combustion influence, smoke influence, and biomass burning, respectively, through 60-s correlation analysis of the increase ratios of CO:CO₂ and CH₄:CO. Combustion efficiency was classified into five levels: high combustion efficiency, medium combustion efficiency, low combustion efficiency, and the lowest combustion efficiency (biological combustion), respectively, through 60-s correlation analysis of the increase ratio of CO:CO₂.

GEMS V3.0

GEMS V2.0

GEMS v3.0 Ozone is mostly underestimated around the tropopause, and tends to be overestimated in the middle stratosphere.

Summary

- SIJAQ data is being thoroughly validated and is expected to be released by November this year.
- In-depth analysis of ground/airborne/remote/modeling data is being conducted for winter PM formation and GEMS validation.
- The Korean RSSR team has been formed and will begin work in earnest in September.
