1. Motivation

- 30,000 premature deaths per year are presently attributed to air pollution in South Korea.¹
- CO**, **SO₂**, and **NO₂** have decreased continuously, achieving **>99% attainment**.
- Surface **O₃** and **PM_{2.5}** exceed air quality standards, and O₃ is **increasing** (0.4 ppbv a⁻¹).
- Satellite observations** offer a new resource for monitoring air pollutants and trends.
- We **analyze recent (2015–2023) trends** and demonstrate the synergy between surface and satellite observations.
- We **diagnose O₃ and PM nitrate (NO₃⁻) sensitivities** to guide control strategies.^{2,3}

2. Data

- Emissions: Clean Air Policy Support System (CAPSS)
- Surface: AirKorea ground network
- Satellites: LEO and geostationary instruments

Instrument Operation Observations

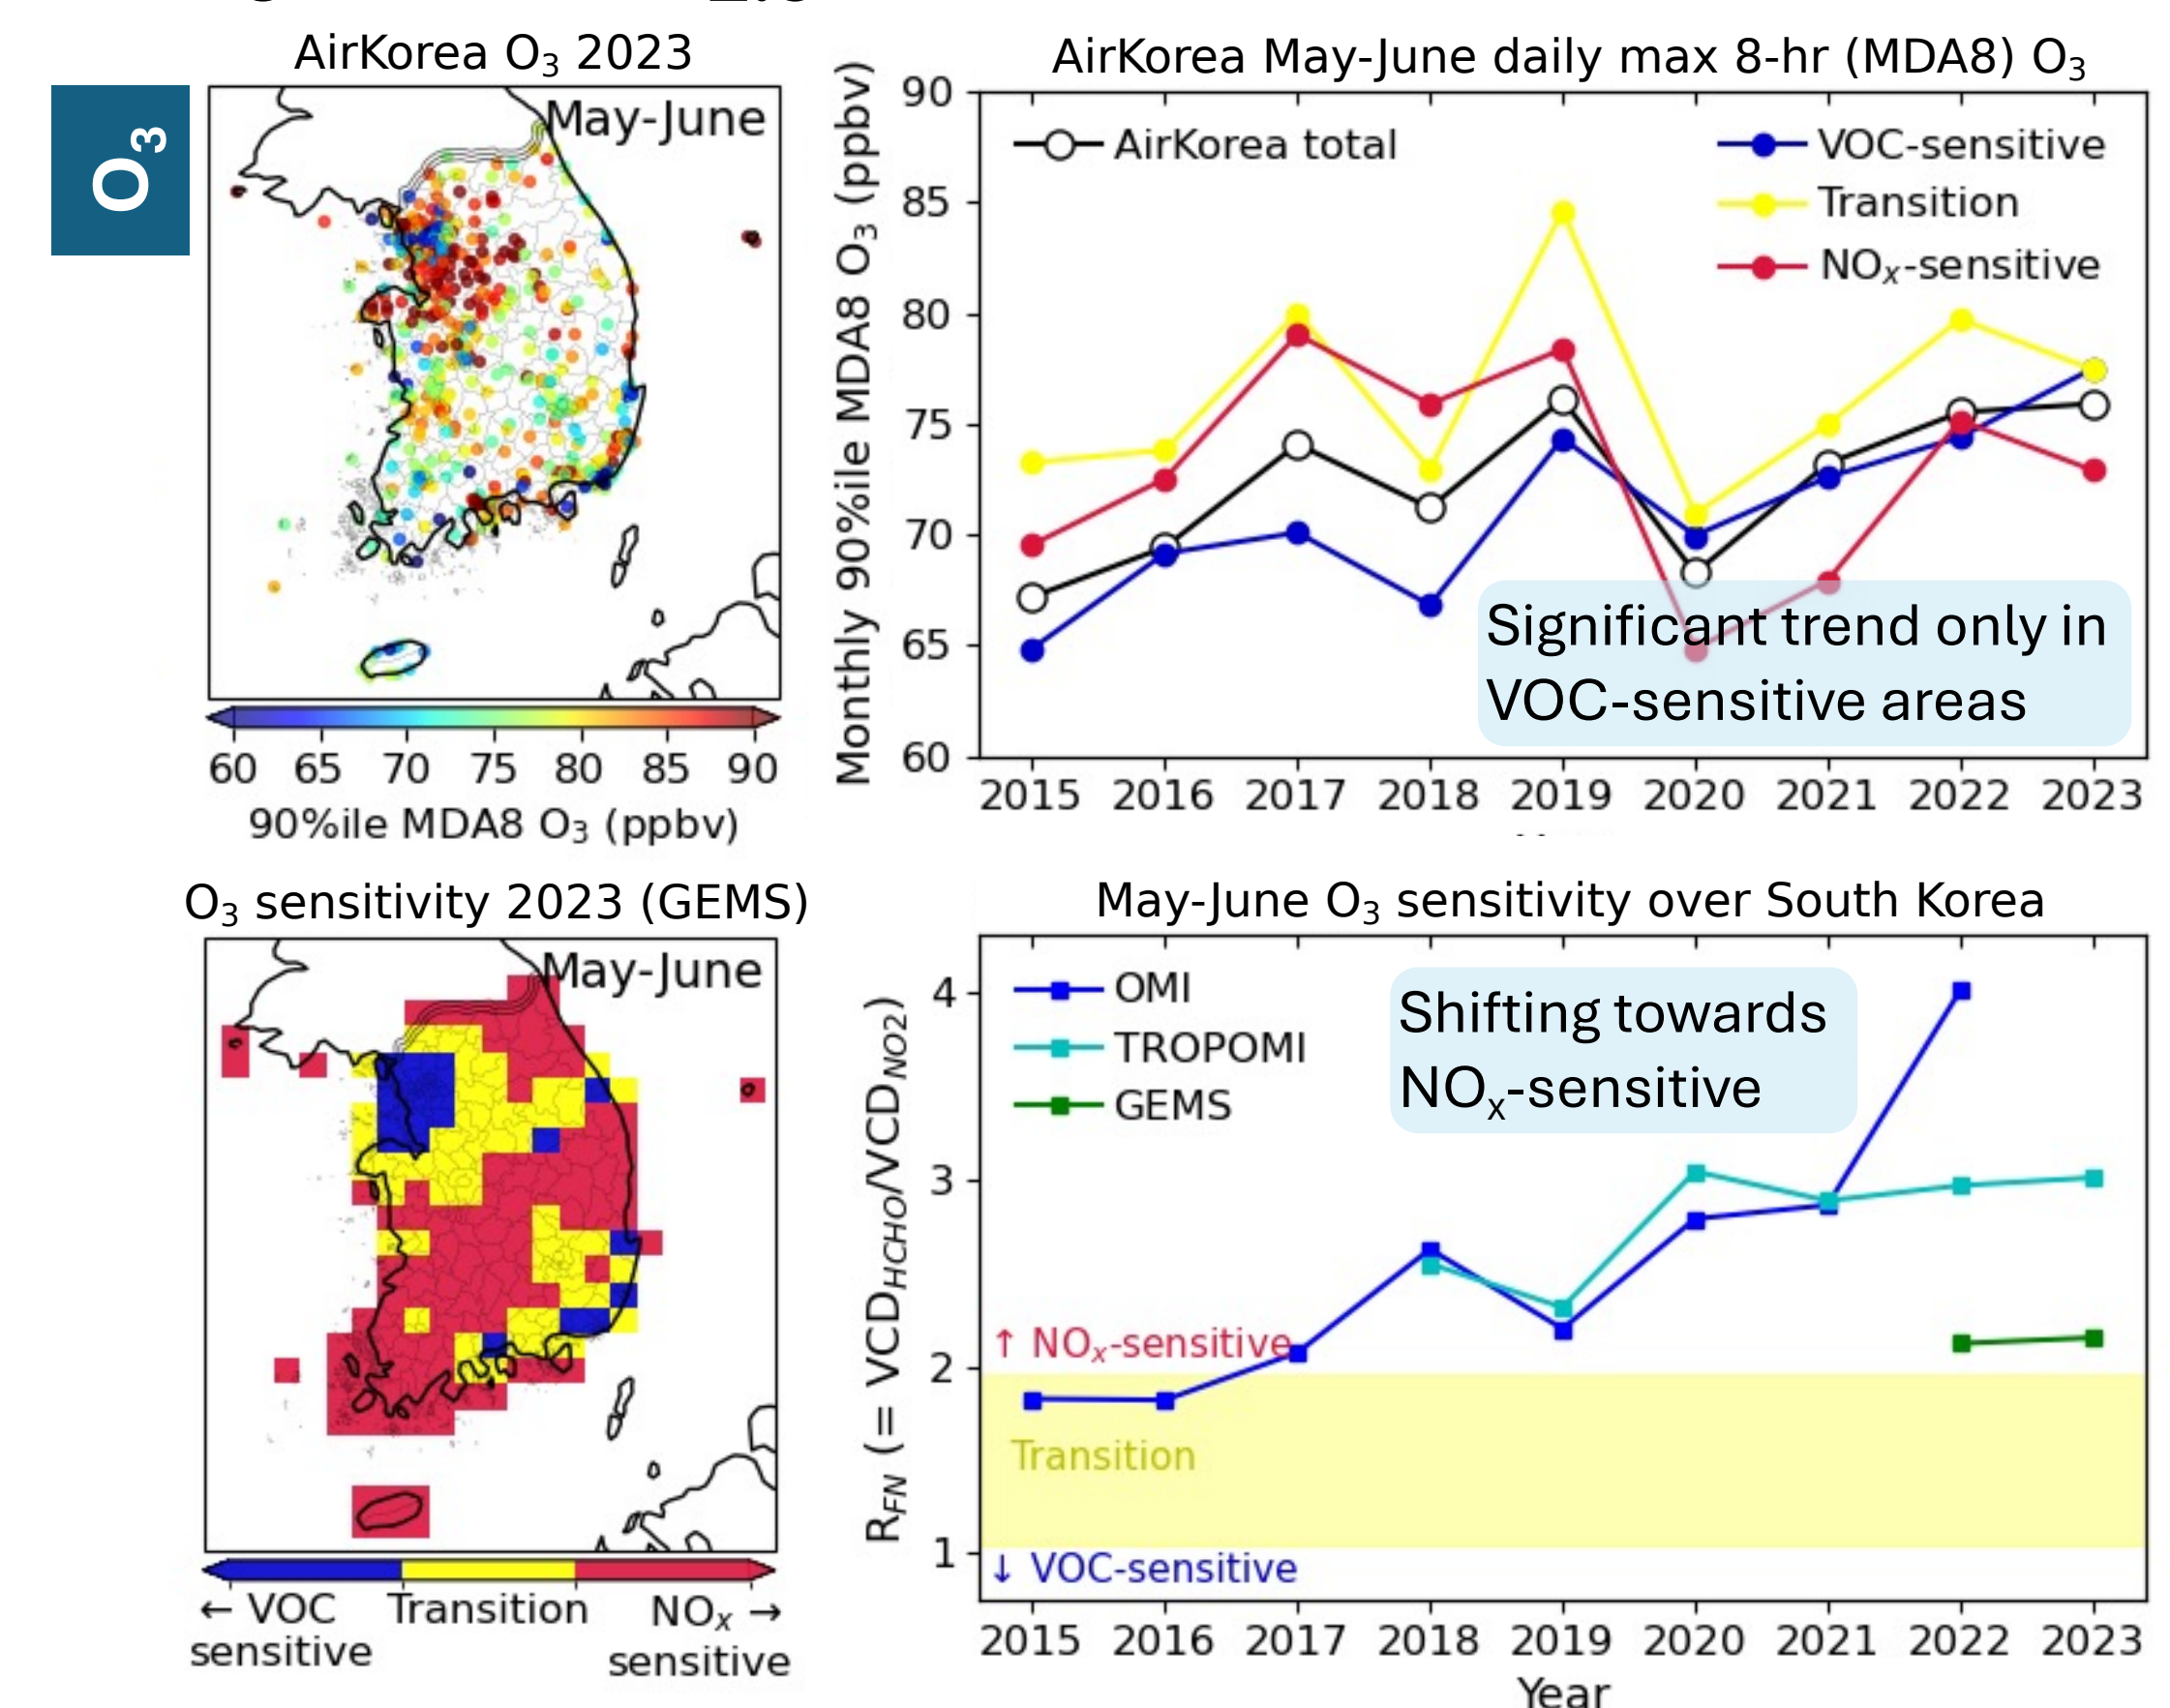

Low Earth Orbit (LEO)

MOPITT	1999–	CO vertical column density (VCD)
OMI	2004–	SO ₂ , NO ₂ , HCHO VCDs
TROPOMI	2017–	CO, NO ₂ , HCHO VCDs
IASI	2006–	NH ₃ VCD

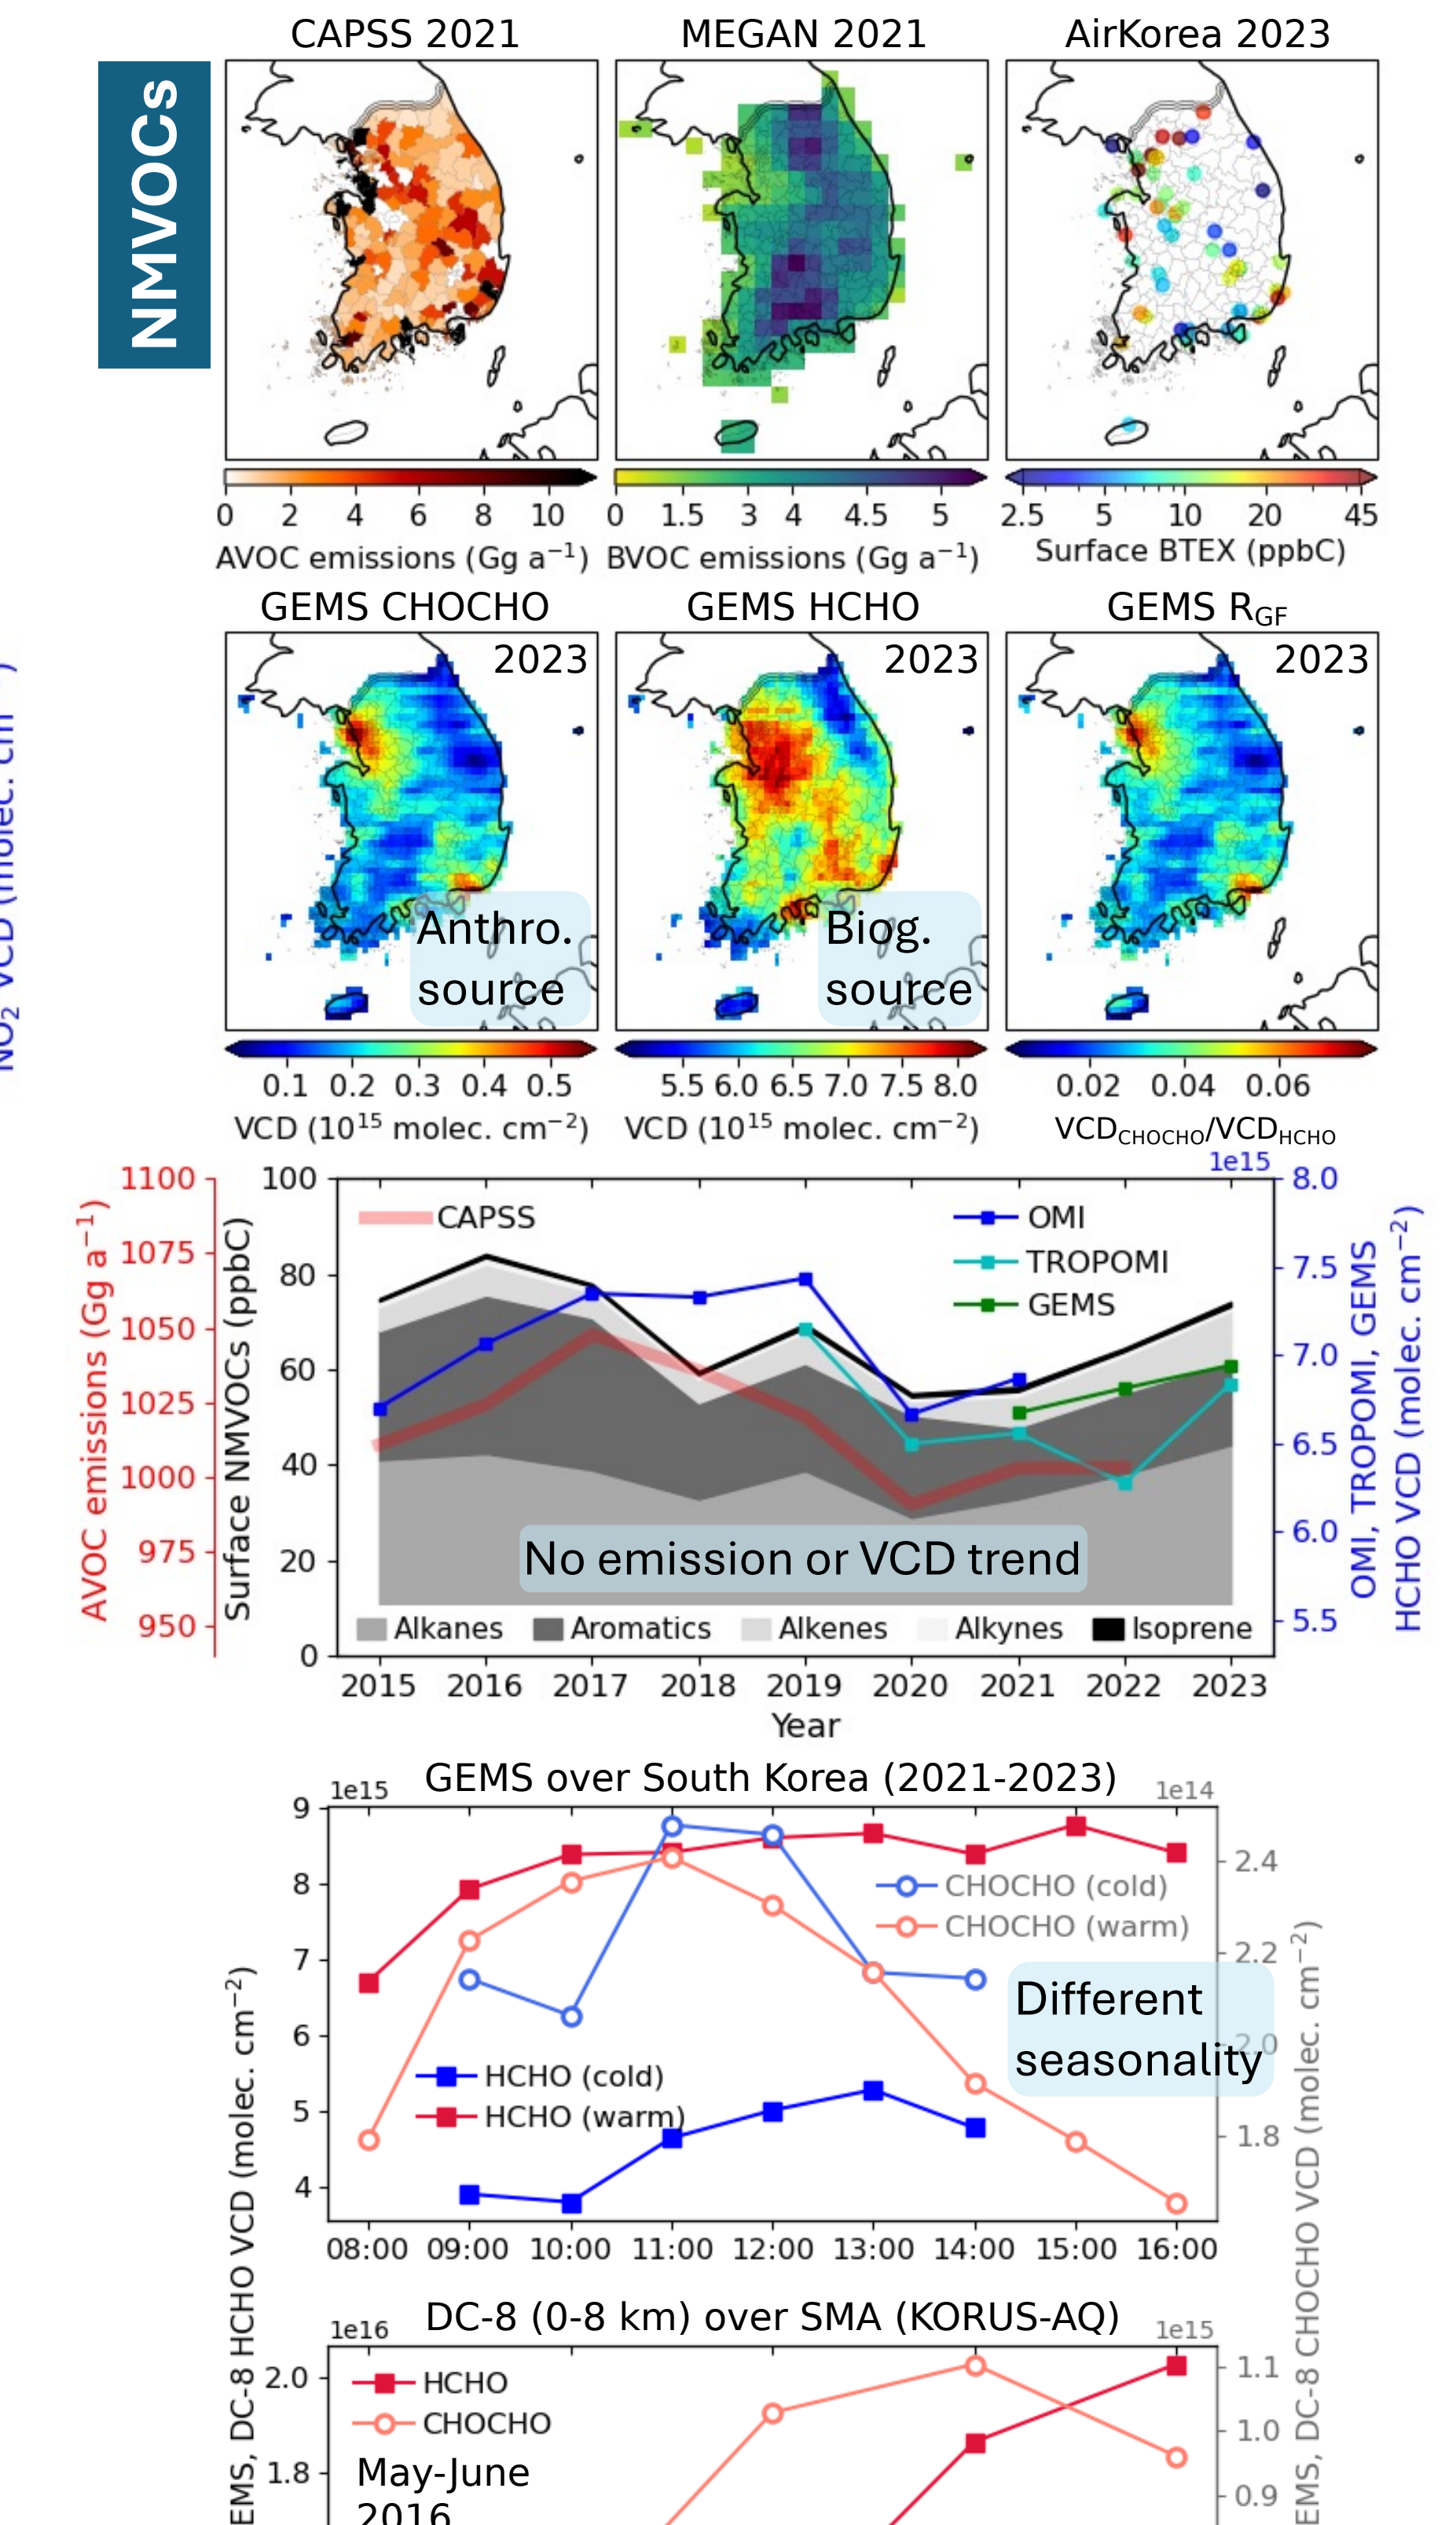

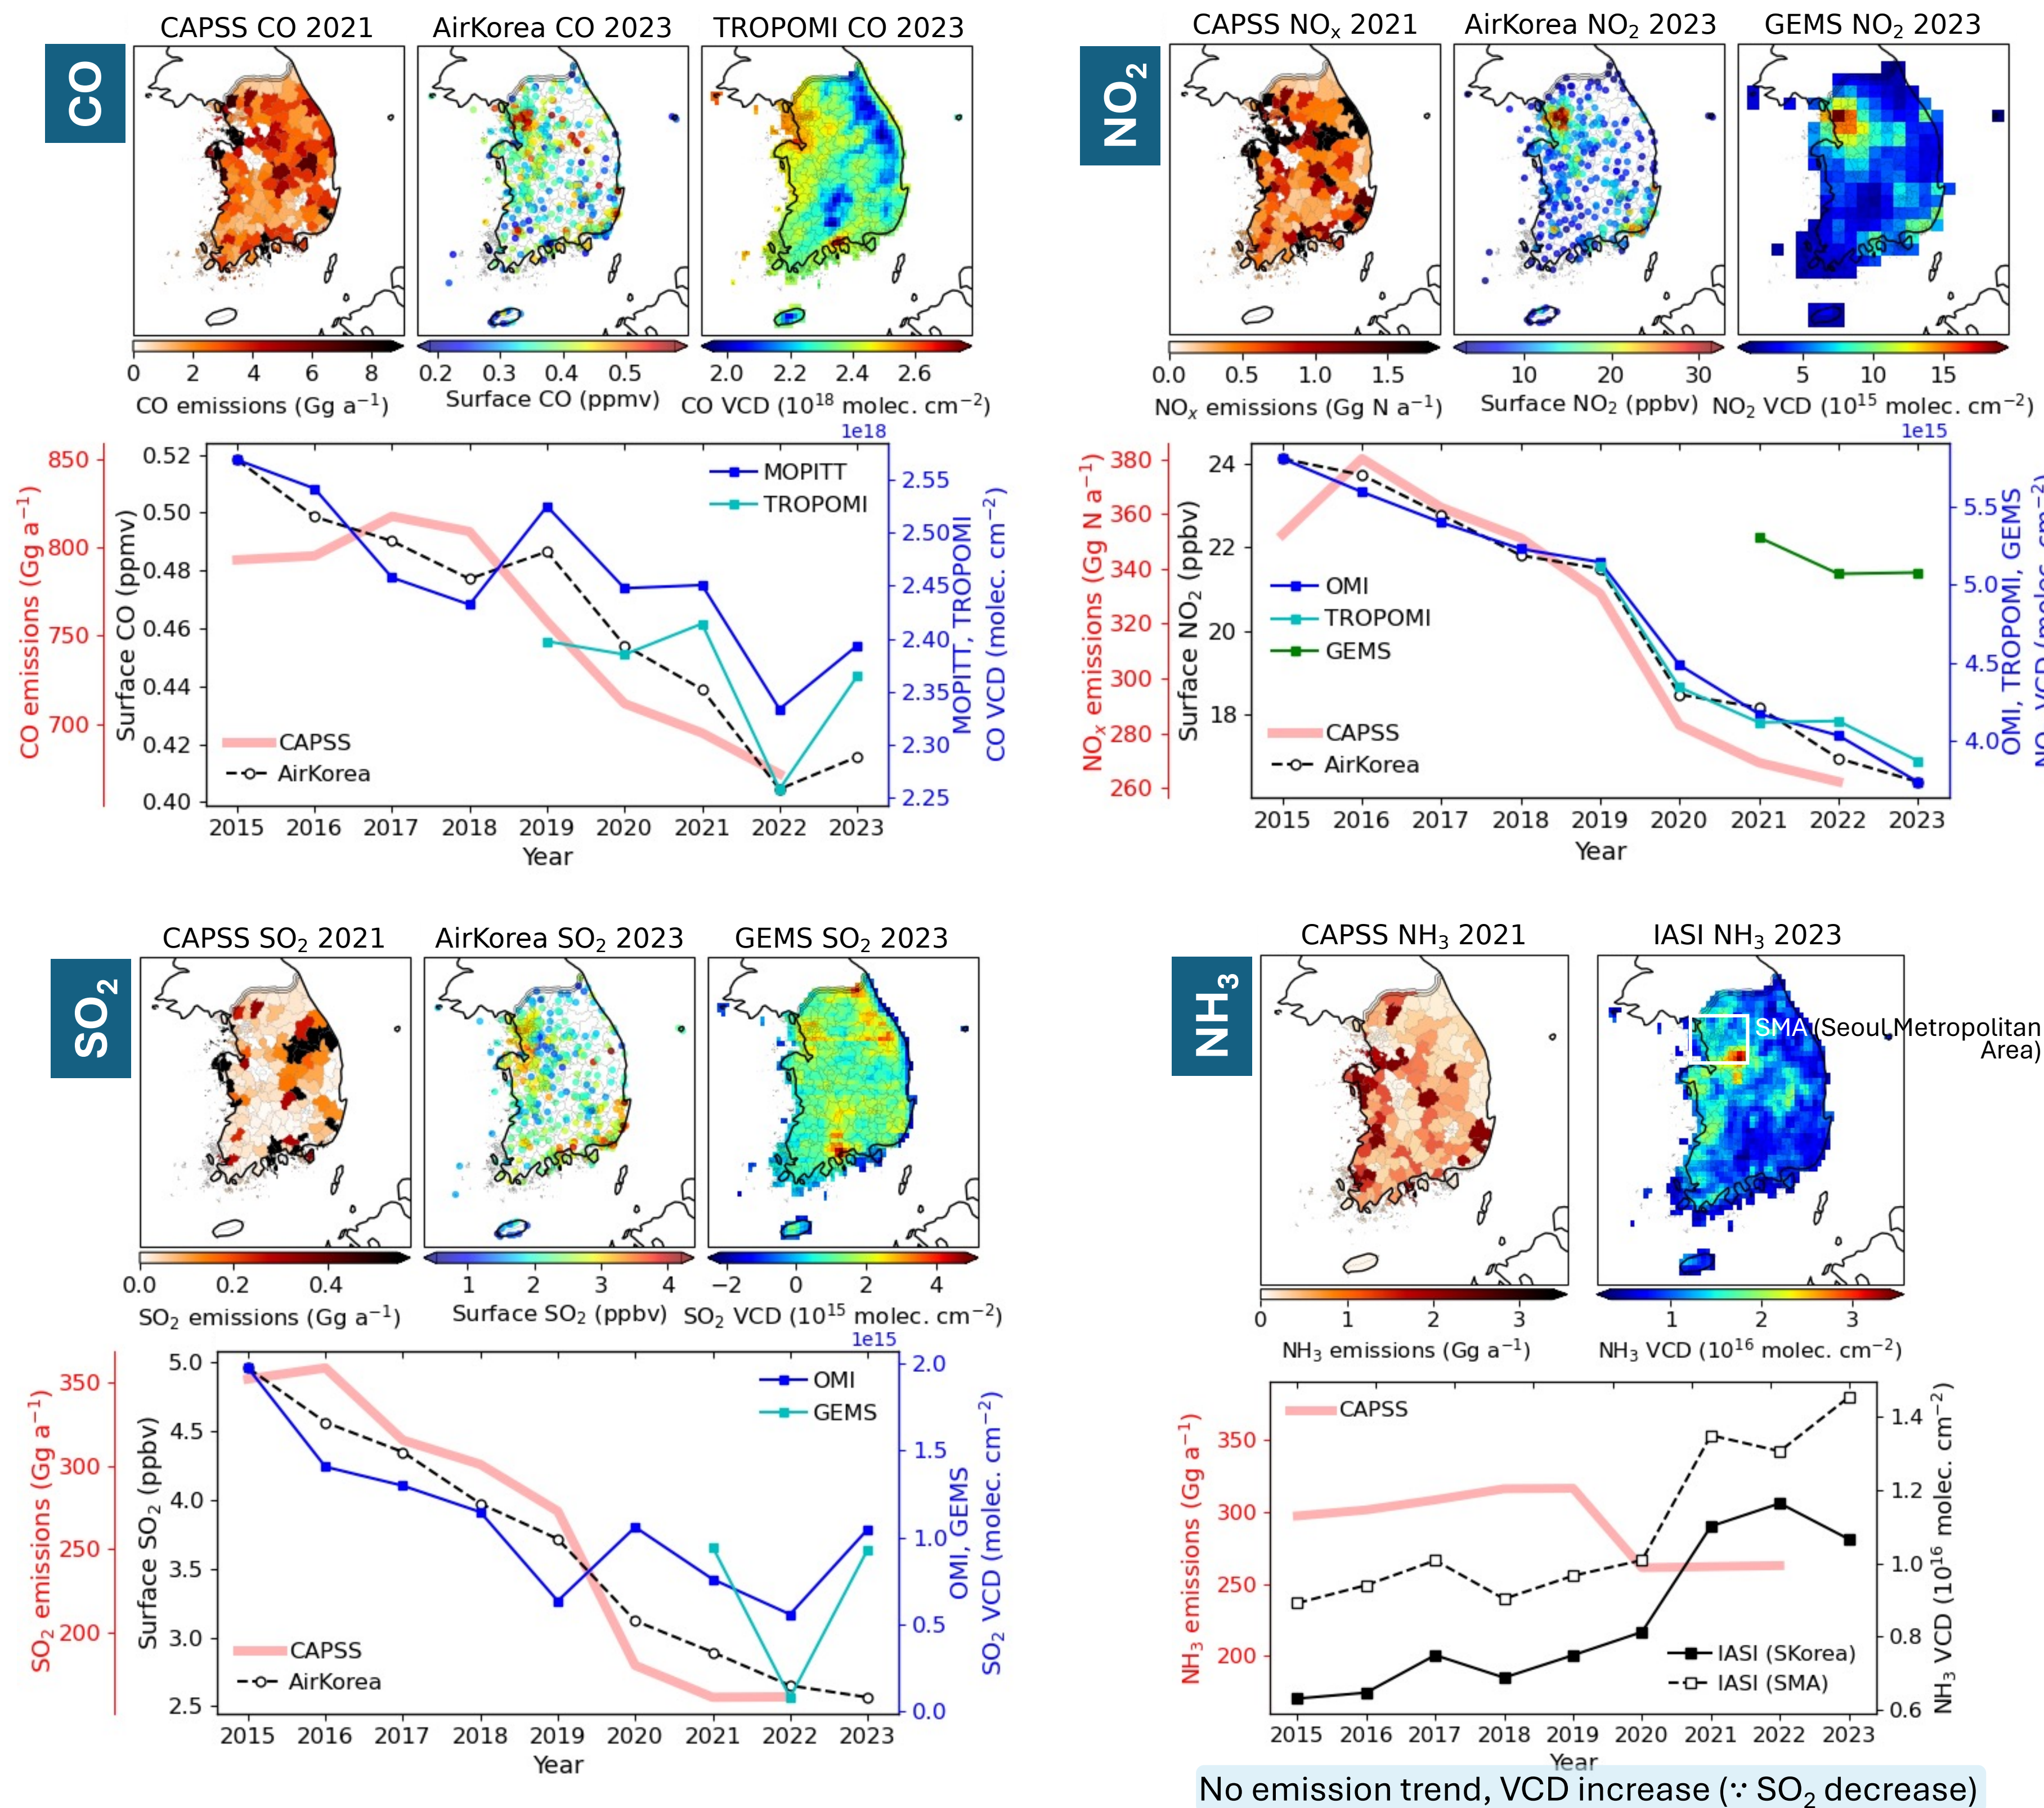

Geostationary Orbit

GEMS	2020–	SO ₂ , NO ₂ , HCHO, CHOCHO VCDs
GOCI	2011–21	AOD (aerosol optical depth)
GOCI-II	2020–	AOD

4. O₃ and PM_{2.5} sensitivities and implications for control strategies

3. Precursor distributions and national trends

Implications

- Satellite HCHO/NO₂ and NH₃/NO₂ indicate a recent shift of both O₃ and PM_{2.5} towards NO_x-sensitive regimes.
- Continued decrease in NO_x emissions will help improve both O₃ and PM_{2.5}.
